Summary

Studies carried out in 2001–2003 were aimed at evaluation of the current structure and conditions of the population along with the recording of biometric traits of downy willow specimens at their natural stand on Lake Bikcze.

It has been found that the population of downy willow on the peat bog near Lake Bikcze has much increased since the 1950's. The character of phytocoenoses, where *Salix lapponum* occurred most abundantly, may prove its wide requirements in terms of habitat conditions. *S. lapponum* specimens were in good condition. Furthermore, blooming of male and female specimens as well as great viability of pollen grains was recorded. High variability of selected biometric traits for studied species' specimens was found.

Key words: *Salix lapponum*, population's structure, condition, biometric traits

INTRODUCTION

Boreal species of vascular plants make up a relatively large percentage in the flora of Łęczyńsko-Włodawskie Lakeland: there are 149 species on over 1000 stands (in peat bog, aquatic, forest, and xerothermic ecosystems). Most of those stands are located at the edge of the geographic range of boreal species (M i t k a , 1997; F i j a ł k o w s k i and L o r e n s , 1998).

Despite of the fact that many rare plant species enjoy complete legal protection, most of them are threatened with extinction, which is associated with their low tolerance towards changing habitat conditions (K a ż m i e r c z a k o w a and Z a r z y c k i , 2001).

Salix lapponum L. (downy willow) is boreal relict, a rare and extremely threatened species due to a gradually decreasing number of its stands as well as an alarming decrease of its population in Poland (K a ż m i e r c z a k o w a and Z a r z y c k i , 2001). The largest number of its lowland stands remained within Łęczyńsko-Włodawskie Lakeland. The first and only

(in the 20th century) study on downy willow ecology and distribution was made just for that area in 1958 by F i j a ł k o w s k i . His observations have not been verified up to date, meanwhile in 1996 *Salix lapponum* was considered to be a species threatened by extinction in the Lublin region (F i j a ł k o w s k i , 1996).

Within Łęczyńsko-Włodawskie Lakeland, the most numerous population of *S. lapponum* can be found on Lake Bikcze. The present study was aimed at evaluating the current structure and condition of that population, as well as documenting biometric traits of downy willow specimens.

MATERIALS AND METHODS

The observations were made in 2001–2003 on the peat bog adjacent to the western edge of Lake Bikcze in Łęczyńsko-Włodawskie Lakeland.

The first stage of the study consisted in determining 7 research plots (A, B, C, D, E, F, G) of size (60–750 m²) and shape dependent on the quantity and distribution of *S. lapponum* specimens in particular peat bog fragments (Fig. 1). Detailed floristic lists were made and analyzed in syntaxonomic view to characterize phytocoenoses in the studied area. Current botanical nomenclature was given after M i r e k et al. (2002), and phytosociological one after M a t u s z k i e w i c z (2001).

Following procedures were made in every area in order to record the quantity and quality of the downy willow population:

- the number of *Salix lapponum* specimens in the studied area and its surroundings;
- the condition of *Salix lapponum* in its stands using original subjective 3-grade shoot status classification taking into account characteristic conformation and general health of plants (P o g o r z e l e c , 2004);
- the ratio of female to male *S. lapponum* specimens (during the blooming at the end of March and the beginning of April 2003);

- pollen grains of *Salix lapporum* were collected in April 2004; it served to determine its viability. Typical acetocarmine microscopic preparations were made using fresh pollen at the collection site. Acetocarmine dying protoplasts of live pollen grains to red color allowed for excluding their sterility. The preparations were analyzed using a light microscope. The percentage of live pollen grains was calculated. In order to decrease errors to a minimum, 2 preparations were made from each of 7 samples, and then every 300 grains were analyzed in each.
- biometric measurements of over 100 plants were made taking into account the following: stem height, height of leafy top of stem, number of leaves, length and width of leaf located in the middle of stem (at 0.1 cm accuracy).

Every above-ground stem, regardless of the underground connections, was considered as a specimen.

The survey was updated every year focusing on changes in stems of the *S. lapporum* population in each research stations as well as changes in the plants' condition in the studied populations.

General characteristics (median, lower and upper quartiles, range, minimum, and maximum values) were calculated for variables measured in the quotient scale.

RESULTS

The population of downy willow on Lake Bikcze has much increased since the 1950's. A total of over 5000 specimens were recorded in 2001-2003 (Tab. 1). The stand of the studied species was located on a transitional bog. *Salix lapporum* occurred most frequently together with plant species characteristic for associations from *Phragmitetea*, *Scheuchzerio-Caricetea nigrae*, *Chycoc-*

co-Sphagnetea, *Molinio-Arrhenatheretea*, and *Alnetea glutinosae* classes (Tab. 2, Fig. 2).

Evaluation of particular downy willow specimens revealed their general good condition, which slightly oscillated during two-year observations (Tab. 1, Fig. 3).

Specimens of *Salix lapporum* bloomed and fruited in all the plots and the whole stand on Lake Bikcze (Figs 4, 5); the determination of sex structure within the population was then possible. Female specimens dominated at the ratio of 3:2 in the whole population (Tab. 1).

The pollen grain viability study indicated that it was often higher than 90% in the samples, which proves that there was a possibility of sexual reproduction within the studied population.

Great differentiation of *Salix lapporum* stem architecture was observed in the stand on Lake Bikcze. The height of the above-ground part of stems varied from 25 to 155 cm, which probably depended on the age and light access in the habitat. The length of the leafy stem's top was from 7 up to 85 cm, which depended on the plant's age (older plants produce more side shoots located in the upper fragment of the main stem). The number of leaves in the studied species ranged from 40 to 450 and depended on the development level of the leafy stem's top which is usually more branched and has more leaves in older specimens. A highly significant statistical association between stem height and number of leaves on them was found: the dependence is proportional – the higher plant, the more leaves it produces. The length of leaves sampled from the middle part of the stem varied (from 2.5 to 8.9 cm), and their width was 1.63 cm, on average (Tab. 3).

Table 1
Salix lapporum in research stations on Lake Bikcze.

Study area		A	B	C	D	E	F	G
Size of study area (m ²)		600	750	60	370	330	200	160
Number of shoots	2001	223	8	10	3000	394	111	200
	2002	341	8	10	3514	396	111	235
Maximum height of shoots (cm)	2001	110	120	110	180	95	135	200
	2002	120	90	100	130	130	145	155
Specimen condition (1-3)	2001	2	3	3	3	2	2	2
	2002	2	2	2	3	3	2	1
Ratio of female to male blooming shoots ♀:♂	2003	2:3	0:1	2:1	1:1	3:1	3:1	1:0

Table 3
Descriptive statistics of morphometric traits of *Salix lapporum* specimens in the stand on Lake Bikcze.

	Number of samples	Mean value	Standard deviation	Median	Lower quartile	Upper quartile	Min	Max
A Height of above-ground part of shoot (cm)	104	81.34	27.11	80.00	60.00	100.00	25.00	155.00
B Height of leafy top (cm)	104	36.29	15.02	35.00	26.00	46.50	7.00	85.00
B : A	104	0.46	0.17	0.44	0.36	0.57	0.12	0.89
C Leaf length (cm)	104	5.16	1.31	4.90	4.20	6.10	2.50	8.90

DISCUSSION

Fijałkowski (1958) took note of the fact that *Salix lapporum* stands were located mainly on hardly accessible areas, not damaged due to human activity. In the author's opinion, favorable conditions, mainly dependent on the system of ecological factors that make the

downy willow development easier, occurred most often on the lake's edge (probably primary stands), rarely on wide peat bogs (probably secondary stands). The largest arrangements of downy willow were described on peat bogs adjacent to Lakes Białe Sosnowickie, Czarne Gościnieckie, Miejskie, Gumienko, Orzechówka, Moszne, Długie, Wytyckie, Łukie, Spilno-Koseniec, and Dubie-

czyńskie. Fijałkowski (1958) recorded the occurrence of *S. lapponum* in small groups from 10 to 50 specimens on the peat bog near Lake Bikcze.

The original studies carried out in 2001-2003 confirmed the occurrence of a much larger population of downy willow in the studied area (about 5 000 specimens). *S. lapponum* specimens were characterized by good condition, which may prove appropriate habitat conditions for its growth and development in the studied stand.

The reason for the population increase might result from the change of habitat conditions associated with hydrotechnical reconstruction of that area. Lake Bikcze is situated in a wide depression of agriculturally used area near the village of Rozplucie-Grabów. The lake's

edge (except from its eastern and south-eastern parts) was covered with transitional and valley peat bogs before 1969. The remodelling of the lake's edges associated with the construction of the Wieprz-Krzna Canal caused the isolation of the lake and adjacent peat bog fragments. In 1973 considerable feature changes of the peat bogs inside the ditch and the embankment were observed. The valley peat bogs transformed into transitional ones, and they began to acquire morphological and floristic traits of raising peat bogs (Wojciechowski et al. 1988; Wojciechowski and Fijałkowski, 1998).

The change of the peat bog character probably greatly affected the improvement of the condition of *S. lapponum* and resulted in the population's increase.

The character of phytocoenoses, in which *Salix lapponum* occurred, may prove high requirements of downy willow in terms of habitat conditions, as well as its entering various succession stages.

Blooming of *Salix lapponum* in Łęczyńsko-Włodawskie Lakeland is in early spring (usually the end of March and beginning of April), which is not confirmed by literature data. The generally cited dates in May-June (Bolliger, 1998; Kaźmierczakowa and Zarzycki, 2001; Kłosowsky, 2001; Rutkowska, 2001) probably refer to specimens growing in the center of the dense range of species occurrence (Finland) where climatic conditions are quite different from those observed here (Podbielkowska, 2002).

Fijałkowski (1958) found that light accessibility apparently affected the conformation and height of downy willow plants; light deficiency was unfavorable, and any activity associated with tree logging and maintenance of peat bog at the thicket stage favored the settlement and development of downy willow. He also determined the classes of *Salix lapponum* condition, with shrubs up to 1.5 m height, strongly branched and leafy, considered as the most ripe. Such specimens, according to the studies from 2001-2003, can be found mainly in shady stands, which seems to indicate the connection of the plant's overgrowth with light competition. It is extremely apparent on the peat bog on Lake Bikiče where *Salix lapponum* growing along with high shrubs and trees reaches up to 2 m, meanwhile at some distance in open area, specimens of only 1 m height can be seen (acc. to Rutkowska, 1998, it is a standard height). Low and inconspicuous shrubs (only to 1 m of height) occur mainly in unshaded stands where habitat conditions are most similar to natural habitats in the center of the dense range of species occurrence.

Downy willow shows great variability of leaf size, plant height, and shape of leaf blade. Fijałkowski (1958), when describing the variability of *Salix lapponum*, found that the two former traits were closely associated with the habitat change, while the leaf blade shape did not show any of these dependencies, because it resulted from the formation of distant hybrids (mainly with *S. cinerea* and *S. pentandra*).

It was observed during the studies in 2001-2003 that a specimen's height depended on the competition for light with other species, and similarly to the leaf size and shape, on the age of the studied plants.

The reasons for such great differentiation of morphometric traits, namely the leaf blade shape in *Salix lapponum*, not only in different, but also in the same stands, were not univocally recognized as an effect of crossbreeding with other willow species. Observations made during *Salix lapponum* blooming at the end of March and beginning of April 2003 did not

confirm simultaneous blooming of other willow species accompanying in the stands of the studied species, which excluded the possibility of its pollination with other pollen. However, due to a short study period which included only 3 spring-summer seasons, it could not be concluded that such a process had not occurred in the past and that the seasonal isolation mechanism in the stands within Lubelskie Polesie is a continuous process.

The hypothesis that the studied species grows mainly in a vegetative way in our conditions, which would greatly exclude the possibility to produce inter-species hybrids, was not verified (Kaźmierczakowa and Zarzycki, 2001). Blooming of both male and female specimens in the studied stand as well as great pollen viability did not allow excluding sexual reproduction processes within the downy willow population.

Populacja wierzby łapońskiej (*Salix lapponum* L.) na torfowisku nad jeziorem Bikcze (Pojezierze Łęczyńsko-Włodawskie)

Streszczenie

Celem badań prowadzonych w latach 2001-2003 było określenie struktury i kondycji populacji, a także dokumentacja cech biometrycznych okazów *Salix lapponum* (wierzby łapońskiej) w jej stanowisku nad jeziorem Bikcze.

Stwierdzono, że liczebność populacji wierzby łapońskiej na torfowisku nad jeziorem Bikcze znacznie wzrosła od lat 1950. Charakter fitocenoz, w których najczęściej występowała *Salix lapponum* może świadczyć o szerokiej amplitudzie jej wymagań w stosunku do warunków siedliskowych. Osobniki *S. lapponum* charakteryzowały się dobrą kondycją, odnotowano kwitnienie zarówno okazów męskich jak i żeńskich oraz stwierdzono dużą żywotność ziaren pyłku *S. lapponum*. Udokumentowano również dużą zmienność wybranych cech biometrycznych osobników badanego gatunku.
