Abstract

Species of the genus *Orobanche* (Orobanchaceae), parasitic on *Centaurea* in Central Europe, were previously considered to belong to the *O. elatior* group. At present, the taxon is differentiated into two species, *O. elatior* Sutton and *O. kochii* F.W. Schultz. The paper presents for the first time the distribution of *O. elatior* and *O. kochii* in Poland based on a critical revision of herbarium and the literature data, as well as the results of field studies conducted between 1999 and 2014. The majority of the species' localities are in south Poland: Silesia-Cracow, Małopolska and the Lublin Uplands. The distribution of both species in Poland is mapped and chronologically organized, and is thus the most recent in Europe. The taxonomy, host preferences, and ecology are also discussed. Seeds of both species were also investigated using light and scanning electron microscopy, which resulted in the designation of diagnostic features. The new color form of *O. kochii* f. *citrina* is described and illustrated. An account of all revised herbarium specimens collected from Poland, deposited in Poland and neighboring countries, is presented.

Keywords: *Orobanche elatior*; *Orobanche kochii*; taxonomy; distribution; phytocoenoses; SEM

Introduction

Orobanche and *Phelipanche* (syn. *O.* sect. *Trionychon*), are the largest genera in the Orobanchaceae family, and comprise more than 200 species, that lack chlorophyll and are root holoparasites of other vascular plants. Broomrapes are subcosmopolitan, with largest number of species being found in the warmer parts of the Mediterranean, Northern Africa, North America and Western and Central Asia. Several representatives, like *P. ramosa*, *P. aegyptiaca*, and *O. crenata*, parasitize important crops, e.g. tomatoes, tobacco, carrots [1–3]. In Europe they usually grow in the warmest regions, mostly in the Mediterranean countries. On the contrary, in central and northern parts of Europe the genera comprise about 30 species (17 established and 2 ephemeral species from Poland), which are mostly rare, endangered or declining [e.g. 2,4–20]. These parasitic genera consist of plants, which possess very reduced vegetative organs and are highly variable. They are widely known for notorious difficulties in identifying, especially in herbarium material. For these reasons, there are a lot of erroneous determinations of species.

Research into the species of the genus *Orobanche* parasitic on *Centaurea scabiosa*, previously considered as *Orobanche elatior* group, in Central Europe revealed the existence of two distinct and unrelated species. Their proper names proved to be *O. kochii* F.W. Schultz and *O. elatior* Sutton [21]. *Centaurea scabiosa* is the main host of *O. kochii* although single records have been reported on *C. jacea*, *C. tenuifolia*, *C. triumfettii* subsp. *axillaris*, *C. stoebe*, *C. sadleriana*, *C. montana*, and *C. ruthenica*; *O. elatior* is mainly parasitic on *C. scabiosa* and sporadically on *C. jacea* and *C. tenuifolia* [9,13,21–23]. It is interesting that two separate species parasitize the same host and some unrelated broomrapes have been found to parasitize the same host, e.g. *Phelipanche bohemica* (syn. *O. bohemica*), *P. arenaria* (syn. *O. arenaria*), *O. coeruleascens*, or *O. artemisiae-campestris* on *Artemisia campestris*. Different species of the genus *Artemisia* are known as hosts of over 20 species of the genera *Orobanche* and *Phelipanche* [1].

Prior to studies conducted by Zázvorka [21], the name *Orobanche elatior* had been commonly used for over 100 years for an undifferentiated taxon of Eurasian distribution extending from Britain to China [1,2,24,25]. The distribution area of *O. elatior* (excluding *O. kochii*) is restricted to Western and Central Europe, also Nordic and Baltic countries. *Orobanche elatior* occurs mainly in England, the Netherlands, southern Sweden, southern Norway, Denmark, Switzerland, France, Italy and Germany, while eastwards its distribution

Handling Editor: Zygmunt Dajdok

area reaches the Baltic states, Poland, Slovakia, the Czech Republic, Slovenia, Romania [13,21,23] (also Piwowarczyk unpublished data, and <http://www.nahuby.sk>). Its distribution eastwards is not yet known precisely. It is a rare species in the whole range.

Orobanche kochii is more common. It is Eurasian, continental species stretching from Central Europe to Central Asia, central China and India. Its distribution in Europe covers southeastern France, Italy, Austria, Hungary, the Czech Republic, Slovakia, Poland, Slovenia, Croatia, Serbia, Bosnia and Herzegovina, Romania, Bulgaria, Greece, Ukraine and European Russia. The species may occur in the Caucasus, Siberia, up to Central Asia and the Himalayas ([e.g. 13,21,23,26–30]). Distribution maps of *O. kochii* and *O. elatior* in Central Europe are included in the study by Zázvorka [21].

In Central Europe, the two species are primarily noted in xerothermic habitats, i.e. xerothermic grasslands of the class *Festuco-Brometea* and thermophilous fringes of the class *Trifolio-Geranietea sanguinei*, developed on limestone, marl, basalt, loess, at altitudes 200–750 m. *Orobanche elatior* is found in more semixerothermic and mesophilous communities mostly of the alliances *Arrhenatherion* and *Bromion erecti*, while *O. kochii* is encountered in more typical xeric steppe habitats [21]. The highest localities of *O. elatior* s.l. in Europe have been reported from the Swiss Alps at 1800 m and from Asia up to 2440 m [1,2].

The aim of this study was to identify the distribution of *Orobanche elatior* and *O. kochii* in Poland based on field investigations and verified herbarium and literature data. Preferred habitats, communities, hosts, taxonomic problems and threats to both species are also discussed. The new color form of *O. kochii* f. *citrina* is also described and illustrated. The objective of the present study is to investigate the micromorphology (SEM) of seeds of *O. elatior*, and *O. kochii* in order to establish if there are any micromorphologic characters diagnostic for the investigated taxa.

Material and methods

Study area

Field research was carried out in Poland in the xerothermic areas of the greatest concentrations of *Orobanche* s.l., i.e. in the Silesia-Cracow and Małopolska, and Lublin-Lviv, Volhynia Uplands, Polesie, Lower Oder and Vistula River, the Carpathian Mts and Carpathian Foothills, Sudetes Mts. The field investigations were conducted in 1999–2014, but mostly in 2006–2014. In parallel, the first author revised all the herbarium materials of *O. elatior* and *O. kochii* collected in Poland. The materials are deposited in Polish herbaria CHRZ, KRA, KRAM, KTC, KTU, LBL, LOD, POZ, WA, WRSL, the Czech Republic (PR), Hungary (BP), Germany (B, GLM), and in private herbaria. Herbarium acronyms are given after Mirek et al. [31] and Thiers [32].

Relevé data

The study is based on the analysis of phytosociological relevés with the occurrence *O. elatior* and *O. kochii*, according to Braun-Blanquet approach [33] and originating from

Poland. We performed more than 100 phytosociological relevés, but in this paper we presented the 39 (20 for *O. elatior*, 19 for *O. kochii*) most representative or significant. The nomenclature of vascular plants follows Mirek et al. [34]. The nomenclature of syntaxa is based on Matuszkiewicz [35].

Data processing

The localities of the both species are listed alphabetically as ATPOL cartogram units (10×10 km) based on Zająć [36]. Only localities recorded in our observations and identified or confirmed as well as verified herbarium data are listed. Published data not confirmed by us in the field or undocumented by herbarium materials are not reliable due to frequent determination errors and these incorrect/doubtful localities are listed separately ("List of localities of *Orobanche elatior* and *O. kochii* in Poland" section below) and marked with a special symbol on the map.

Localities are described as follows: ATPOL grid unit, geographic location, habitat description, abundance in brackets. The following information is also given for most localities: geographic coordinates and altitude (above sea level), and for revised exsiccata the collector and collection date, exsiccatum number and the herbarium acronym. Archival maps of western Poland and military maps were used for localities reported in old data (<http://mapy.amzp.pl/maps.shtml>, <http://www.mapywig.org/>).

Symbols and abbreviations: app. – approximately, ATPOL – database, DG – Dąbrowa Górnica, distr. – district, ecol. site – ecological site, exp. – exposure, gras. – grassland, leg. – collected by, n. – near, phot. – photography, res. – reserve, US – University of Silesia database, v. – valley, xer. gras. – xerothermic grassland, vid. – seen by, ? – doubtful locality.

Host analysis

Host plants were observed by delicately exposing the soil with a gardening shovel. A total of 80 soil pits were observed in the field and in the analysis of herbarium materials containing an attached host.

SEM analysis of seeds

Seeds were extracted from 16 samples from 8 localities coming from Poland. The investigated material of *O. elatior* (4 localities: Baldram, Gipsowa Góra, Leszczany, Pińczów) and *O. kochii* (4 localities: Pęczelice, Wesołówka, Toporowice, Boria), has been collected in the field by the first author (see "List of localities of *Orobanche elatior* and *O. kochii* in Poland" section below); these specimens are deposited in KTC. Seeds were extracted from dried plants, mounted on stubs, coated with gold, and examined using a Joel JSM-7400F SEM, at various magnifications. Microscopic observations (LM) were carried out with a stereo microscope NIKON SMZ800 and a biological microscope NIKON Eclipse 50i.

Twelve characters (length, width, and outline of the seed and of the cells on their surface; height, width, and ornamentation of cell walls; presence of a median trough; form and diameter of seed wall perforation) were recorded. For each investigated taxon at least 30 seeds were examined. The terminology of seed surface is given after Barthlott [37,38], Stearn [39], Plaza et al. [40], Bojnansky and Fargasová [41], and Black et al. [42]. The collected data were subject

to elementary statistical procedures [43], the mean, the standard deviation, and the lower and upper quartiles were calculated for each character of each of the three studied taxa. Statistical calculations were performed with Statistica 7.1.

Results

Taxonomic notes

Orobanche elatior Sutton

Orobanche elatior Sutton Transact. Linn. Soc. London 4: 178, 1798 [44]; Syn.: *O. stigmatodes* Wimmer Fl. Schles. 280, 1840 [45]; *O. centaureae scabiosae* Holandre Nouvelle Fl. Moselle, ed. 2, p. 520, 1842 [46]; *O. confusa* F.W. Schultz Fl. Pfalz 339, 1846 et Flora, Regensburg, 30: 66, 1847 [47], nom. inval., in syn. *O. stigmatodes*; *O. major* auct. non L. [48].

Lectotype (Foley 2001: 230): Norfolk, England, herb. Smith 1087.14 n. 1, LINN [49].

Orobanche kochii F.W. Schultz

Orobanche kochii F.W. Schultz Flora Regensburg, 30(5): 66, 1847 [47]; *O. borbasiana* Beck Bibl. Bot. (Monogr. Orobanche) 19: 173, 1890 [26]; *O. elatior* auct. (e.g. Beck in Halácsy et Braun, Nachträge zur Flora von Nieder-Oesterreich, p. 128, 1882) [50], non Sutton; *O. major* auct. non L. [48]; *O. major* f. *typica* Beck, f. *exigua* Beck Bibl. Bot. (Monogr. Orobanche) 19: 170, 1890 et f. *microphylla* Beck l. c., p. 171 [26]; *O. major* f. *moravica* Beck Fedde Repert. 18: 36, 1922 [51]; *O. major* f. *remotiflora* Beck in Engler, Das Pflanzenreich (Monogr. Orobanchaceae) 96 (IV/261): 250, 1930 [27].

Lectotype: “*Orobanche amethystea* Thuill.? Auf mehreren Pflanzen des Gratzer Schlossberges, auch auf *Anthericum ramosum* !! – Blüht im Juli – August wenn an derselben Orten die *O. rubens* et *O. galii* ganz vertrocknet sind. 1840. Dr. Maly” (L, 0835152; cf. [21]).

The interesting history of *O. elatior* and *O. kochii* goes back to 1840 when Maly collected a specimen from Austria and included it into *O. elatior* Sutton [52] but later changed the identification to *O. amethystea*. Maly sent the specimen to Koch, who determined it as *O. stigmatodes* Wimmer in 1844. Koch forwarded the same material to Schultz, who described a new species, *O. kochii* F.W. Schultz, based on it in 1847 [47]. Schultz was the first to distinguish *O. stigmatodes* (= *O. elatior*) from *O. kochii* and also provided a key to their determination. Bohemian, Moravian and Silesian authors accepted this division and the two species were separated in subsequent studies (e.g. [53–55]).

Wimmer [45] described *O. stigmatodes* parasitic on *C. scabiosa* based on plants collected from Poland (Silesia) from the Góra Gipsowa hill in Dzierżysław near Kietrz. The species has occurred there until now [56]. The morphological description of *O. stigmatodes* and the herbarium material collected by Kelch (GLM, see list of localities) undoubtedly belongs to *O. elatior* Sutton s.str. Two species, *O. elatior* s.str. and *O. caryophyllacea*, have occurred on the Gipsowa Góra hill. A herbarium revision shows that the two species, especially *O. elatior* (e.g. [26,27,54]), have been mistaken with *O. lutea* and *O. alsatica*.

The confusion regarding the separation of *O. kochii* followed the publication of monographs by Beck [26,27], who included a non-homogenous group of taxa parasitic on *Centaurea*, *Echinops* or other Compositae, and even Ranunculaceae, into one species, *O. major* L. The division proposed by Beck was later followed by subsequent authors. Beck included eleven forms into *O. major*, five of which should have been included into *O. kochii* (after [21], see synonyms therein).

Some other forms of *O. major* distinguished by Beck were also later classified as separate species. They include f. *krylowii* (Beck) Beck, which was considered by Russian authors as a separate species, *O. krylowii* Beck, occurring in Russia and Central Asia. It is a parasite of the genus *Thalictrum* (Ranunculaceae) [28,29,57]. Surprising recent studies by Frajman et al. [58] reported *O. krylowii* in Albania, 2500 km of known localities. Based on morphological evidence, nuclear ribosomal ITS sequences, Frajman et al. have shown that the Albanian population belongs to *O. krylowii* and that its closest relative is the European *O. lycoctoni*, but not *O. elatior* as previously thought.

The form f. *ritro* (Grenier at Godron) Beck was considered as a separate species parasitic on *Echinops*, *O. ritro* Gren. & Godr. [59] as early as in 1853. Some botanists treated *O. ritro* as a synonym for *O. major* or *O. elatior* (e.g. [60,61]). Zázvorka [21] includes it as a synonym of *O. kochii*. Recently, Pujadas-Salvà [62] reinstated its species rank as *O. ritro*, and has been adopted by other authors [20]. Carlón et al. [63] used *O. loscosii* to name the Iberian plants identified as *O. ritro*, however, Pujadas-Salvà [64] considers, that this species should be included among the synonyms for *O. ritro*.

Orobanche icterica Pau from the Iberian Peninsula, traditionally synonymized with *O. elatior* Sutton, was recently reinstated for Spain by Pujadas-Salvà et al. [65] as a separate species, parasitizing *C. aspera*, *C. fontanesii* and *Rhaponticoides linaresii*, changing the earlier name *O. leptantha* Pomel [63]. Main differences were presented between *O. ritro*, *O. elatior* and *O. icterica* [62], and *O. icterica* and *O. leptantha* [64]. Further research, including molecular analysis, may be interesting to explain relationship between *O. elatior*, *O. ritro*, *O. kochii* and Iberian species *O. leptantha* and *O. icterica*. Moreover, recently has been discovered the locality of *O. elatior* from Lérida in Spain [63].

The form *hypocoeridis* (Druce ex Beck) Beck, described from the Chanel Islands, is at present classified in *O. minor* subsp. *maritima* var. *hypocoeridis* (Beck) Rumsey, parasitic on *Hypochaeris radicata* [66,67].

Zázvorka [21] rightly renewed the division into *O. elatior* and *O. kochii* after nearly 100 years. During investigations into the genus *Orobanche* in Poland, the first author also noticed a lack of homogeneity of specimens considered as *O. elatior*. Lightly colored specimens with a dense inflorescence were initially treated as hypochromatic plants [68]. The above examples clearly show that many different taxa were placed in *O. elatior* and that this group of species requires further studies. A historical survey of *Orobanche* parasitizing *Centaurea* and the history and taxonomic contents of the related names are briefly discussed in a study by Zázvorka [21].

The most important characters distinguishing

Orobanche elatior from *O. kochii*

Both species are quite easily distinguishable when fresh. The corolla and stem in *O. elatior* are yellowish to ochre to light-brown or dirty-pale-pink (very rarely to dark-purple, rusty black, e.g. locality in Podskale) while *O. kochii* has a characteristic carrot-red to whitish-rosaceous or raspberry coloration (Fig. 1). Other characters are helpful in determining herbarium materials. *Orobanche elatior* is usually a large plant, with dense flowers; the corolla is regularly curved throughout, leaves are long and markedly narrow, linear-lanceolate. *Orobanche kochii* is mainly medium-sized; the corolla back is straighter in the middle, lower leaves on the stem are ovate to triangular, the spike subcylindrical and below lax. The two species also differ by the flowering period. *Orobanche elatior* flowers briefly and early, usually in late June, while *O. kochii* has a long flowering period, from late June until late August. A list of distinguishing characters is given in Tab. 1.

A new form *Orobanche kochii*

Orobanche kochii f. *citrina* R. Piwowarczyk & Ł. Krajewski, f. nov. (Fig. 1).

Lemon-yellow forms of *O. kochii* are found in Boria and Jaworzno-Długoszyn. However, they are sometimes an extremely small part of a normally-colored population (Boria), or comprise 50% of the population (Jaworzno-Długoszyn). The yellow color of the stems in typically pigmented populations was observed during two summer seasons. This new taxon is very similar to typical *O. kochii*, and is compliant with morphometric characters in the description of the plant after Zázvorka [21], parasitizing *C. scabiosa*, but differs significantly by color; in typical *O. kochii* they are red or rosaceous, sometimes pale rosaceous-creamy, whereas in the form *citrina* whole plant are lemon-yellow with brownish leaves and bracts, drying out much earlier than the rest of the stem (Fig. 1). In addition, the *citrina* form individuals are slightly smaller – plants are shorter and sometimes have a shorter corolla. Interestingly, the creamy color corolla and stems are found in *O. ritro*, parasitizing *Echinops*, a taxon considered being a synonym of *O. kochii* [21] or a separate species by some authors [62] (see also “Taxonomic notes”).

TYPE. Southern Poland, Boria (N of Ćmielów), xero-thermic grassland on the slope of the Kamienna river valley, inclination SE, 50°58'15" N, 21°32'53" E, alt. 167 m, 27 June 2013, R. Piwowarczyk (holotype KTC!).

DESCRIPTION. Plants medium-sized, flowering stem simple, (5–)15–25(–40) cm high, lemon-yellow, glandular-pubescent, glands whitish to pale yellow; dried specimens light-brown, cream-brown or cinnamon (do not always retain the lighter color after drying). Leaves broad at the base, ovate-triangular. Inflorescence (5–)12–15(–20) cm long, subcylindrical, tapering to the apex, usually 15–30-flowered. Bracts as long as the corolla or shorter. During florescence the bracts dry out quickly and are light-brown, particularly on their ends, which is very clearly seen in contrast to the lemon-yellow corolla and stem. Calyx segments are free or occasionally connate at base, 12–16 mm long, asymmetrically ovate and unequally bidentate. Corolla lemon-yellow (rarely whitish-yellow, whitish-lemon), (15–)20–28 mm

long, dorsal line curved at the base, than nearly straight, glandular-pubescent, glands pale lemon-yellow or whitish. Stamens inserted 4–6 mm above the corolla base. Style sparsely glandular, stigma lobes deep yellow and usually darker than the corolla. Flowering period (late June) July to August. Parasitizing *C. scabiosa* (in Poland).

DISTRIBUTION AND ECOLOGY. *Orobanche kochii* f. *citrina* is currently known only from S Poland – Małopolska and the Silesia-Cracow Uplands (Boria and Jaworzno-Długoszyn). It is found in xero-thermic grasslands of the *Cirsio-Brachypodion pinnati* alliance, on gentle slopes of hills, on soils rich in calcium carbonate, southern inclination, altitude 160–280 m.

ETYMOLOGY. The form name originated from the lemon-yellow coloring of plants.

PARATYPES. Southern Poland, Jaworzno-Długoszyn E, hill with iron cross SE of church, secondary grassland *Cirsio-Brachypodion pinnati*, inclination SW, 50°14'43" N, 19°15'53" E, alt. 280 m, 4 August 2010, Ł. Krajewski (KTC!).

Seeds micromorphology

Orobanche elatior seeds are oblongoid, rare ovoid or subrectangular, (300–)386(–450) × (190–)242(–320) µm. Epidermal seed coat cells are isodiametric to elongated; rare irregular and elongated, (40–)105(–160) × (30–)59(–100) µm. Perforation diameter ranged (4–)7.9(–13) µm, and its shape is elliptic to subcircular. The narrow trough is always present on the upper side of cell walls and is continuous. The wall width reaches (3–)6.1(–8) µm (Tab. 2, Fig. 2).

Orobanche kochii seeds are oblongoid, rare ovoid or subrectangular, (200–)328(–410) × (130–)206(–300) µm. Epidermal seed coat cells are isodiametric to elongated; rare irregular and elongated, (55–)102(–170) × (35–)52(–90) µm. Perforation diameter ranged (2–)2.7(–4) µm, and its shape is subcircular. The narrow trough is always present on the upper side of cell walls and is continuous, sometimes with ornamentation. The wall width reaches (3–)4.2(–6) µm, pitted, sometimes with additional and less ornamentation (Tab. 2, Fig. 2).

Preliminary results of micromorphological examinations of seeds of *O. kochii* and *O. elatior* (then treated as two forms of *O. elatior* s.l.) have revealed differences in seed ornamentation, especially of the periclinal walls [68]. Our detailed studies demonstrated significant differences of diagnostic importance between *O. elatior* and *O. kochii*. The most important factor is the diameter and shape of the wall perforation. In *O. elatior* the perforation diameter is much larger, 4–13 µm, and is usually elliptical, while in *O. kochii* the diameter is smaller, 2–4 µm, and subcircular. Other characters of seed size and their cells are less important, but the analysis of a larger sample clearly demonstrated that seeds of *O. elatior* are larger than those of *O. kochii* (Tab. 2, Fig. 2).

Determination problems and discriminating from other species

Orobanche elatior belongs to a diversified section *Orobanche* (syn.: sect. /grex/ *Curvatae* Beck) [27], containing about 15 species. However, *O. kochii* probably has a relationship to another section *Minores*, this is supported by morphological characteristics, and preliminary molecular

Tab. 1 The most important characters distinguishing *Orobanche kochii* and *O. elatior* [21] (corrected after our observations).

Characters	<i>Orobanche kochii</i>	<i>Orobanche elatior</i>
Stem, height	Usually (5)20–30(60) cm	Usually (10)30–40(95) cm
Leaves, shape	Broad at base, ovate-triangular	Narrow, elongated, linear-lanceolate
Inflorescence	Subcylindrical (tapering to the apex) and below lax	Cylindrical and dense (often with an additional, narrow, acute top of unopened flower buds)
Corolla and stem, color (in fresh materials)	Carrot red to whitish-rosaceous, raspberry; Rarely also entire plants lemon-yellow; stem usually with stronger coloration, corollas lighter	Deep yellow to pale brown (ochre), pale rosaceous, very rare to dark purple violet (almost black); stem and corolla in the same color
Back of corolla	The middle of the back nearly straight	Regularly curved throughout
Dried specimens	Brownish-rusty, cinnamony, darker	Pale brown (ochre), paler
Flowering period	Lengthy, (late June) July-August (September)	Very short (only 2 weeks), mid-June
Host (Central Europe)	<i>Centaurea scabiosa</i> , occasionally <i>C. stoebe</i>	<i>Centaurea scabiosa</i>

Tab. 2 A comparison of the main characters distinguishing seeds of *Orobanche elatior* and *O. kochii*.

Characters	<i>Orobanche elatior</i>	<i>Orobanche kochii</i>
Seed length (μm)	(300–)386(–450)	(200–)328(–410)
Seed width (μm)	(190–)242(–320)	(130–)206(–300)
Cell length (μm)	(40–)105(–160)	(55–)102(–170)
Cell width (μm)	(30–)59(–100)	(35–)52(–90)
Perforation diameter (μm)	(4–)7.9(–13)	(2–)2.7(–4)
Wall width (μm)	(3–)6.1(–8)	(3–)4.2(–6)
Seed shape	Oblongoid, rare ovoid or subrectangular	Oblongoid, rare ovoid or subrectangular
Cell shape	Isodiametric to elongated; rare irregular	Isodiametric to elongated; rare irregular
Perforation shape	Elliptic, rarely subcircular	Subcircular
Wall depth	Medium	Medium
Wall ornamentation	Pitted or slightly pitted	Pitted, sometimes with additional and less ornamentation
Narrow trough	Evident around cells	Evident around cells, sometimes with ornamentation

evidence (Piwowarczyk et al. unpublished); it was also initially indicated in the work of Carlón et al. [63].

Typical *O. kochii* is clearly distinguished from *O. elatior* and they are easily differentiated. *Orobanche kochii* is a distinctive species and it does not have any morphologically similar taxa in Central Europe. However, *O. elatior*

in Central Europe is similar in morphology to *O. alsatica* and *O. bartlingii*. Some specimens in herbarium materials lacking information on the host are difficult to diagnose. It is crucial to note the host of plants of the genus *Orobanche*, especially for *O. elatior*. *Orobanche elatior* is parasitic on *Centaurea* (mainly *C. scabiosa*), *O. alsatica* on *Peucedanum*

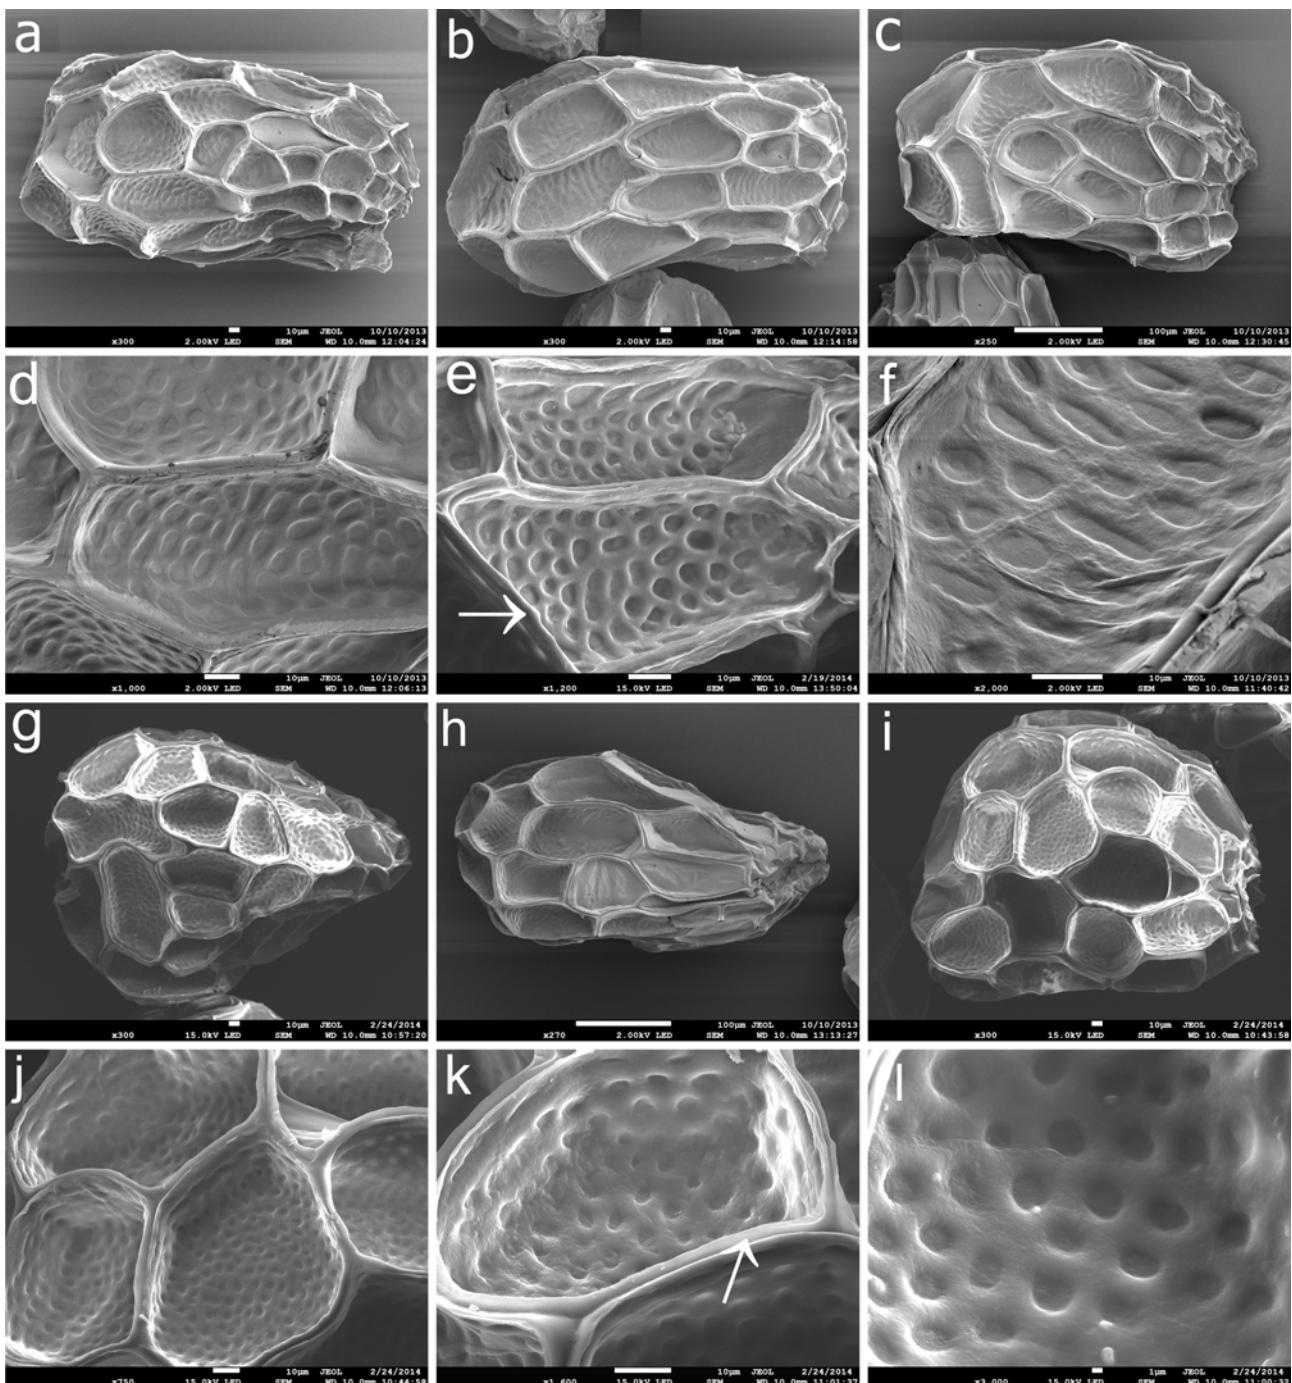

Fig. 2 Micromorphology of seeds of the studied species in SEM micrographs (surfaces). **a-f** *Orobanche elatior*. **g-l** *O. kochii*. **a-c,g-i** – general habit of seeds; **d-f,j-l** – variation of sculpture, perforation diameter and their shape; arrows indicate the narrow trough.

(chiefly *P. cervaria*, sporadically *P. alsaticum*), rarely on *Seseli osseum* and *S. austriacum*, while *O. bartlingii* on *Libanotis pyrenaica*. Even results of molecular studies have revealed close relationships between *O. elatior* and *O. alsatica* [69]. It seems that these relationships will be especially close between *O. bartlingii* and *O. flava*. Incorrect determinations can also be related to *O. elatior* and *O. flava*. However, *O. flava* is evidently distinguished from other taxa by different phytocoenoses, usually mountain hydric scrub on streams, and by parasitism on the genus *Petasites*. Lack of information regarding the host can also cause determination problems.

Monstrous shoots of *O. elatior*, branched into 2–4 inflorescences, with a tape-like stem, multiflorous inflorescence, with incorrectly placed flowers, are encountered occasionally (rarely), e.g. Leszczany in the Lublin region and DG-Błędów in the Dąbrowa Basin. This is probably related to herbicide on farmland near localities.

Distribution in Poland

The revision of and detailed field investigations into *O. elatior* and *O. kochii* in Poland have revealed considerable differences in the distribution, especially in relation

to the previous distribution map of *O. elatior* s.l. [70]. The study also significantly changed and updated the previous distribution map for both species in central Europe prepared by Zázvorka [21].

At present *O. elatior* in Poland mainly occurs in the Silesia-Cracow, Małopolska and Lublin Uplands, rarely in the Lower Vistula Valley, Central Sudetes Mts and the Carpathian Foothills. *Orobanche kochii*, which is more common than *O. elatior*, has numerous localities but almost exclusively in the Polish uplands in a very compact range (Fig. 3, Fig. 4).

Only data verified in the field or confirmed by the herbarium material or photographic documentation is listed below. Due to frequent incorrect determinations, localities reported in the literature and unpublished localities that are not documented by herbarium material and not verified by us in the field are listed separately and marked with a special symbol on the map. Localities in the maps have been differentiated into three time periods, in order to illustrate the most current and the actual state distribution of both species (Fig. 3, Fig. 4).

Many literature reports may not be reliable due to the host they provide, e.g. *Medicago falcata*, where *O. elatior* s.l. was probably mistaken with *O. lutea* and others (e.g. [71–77]). Corrections are also needed for photographs of *O. kochii* [68,78–80] or *O. lutea* [81], captioned as *O. elatior*.

List of localities of *Orobanche elatior* and *O. kochii* in Poland

Orobanche elatior

AC: 30 – Bielinek, leg. R. Schulz 1914, 1925 (B) [82–85]; E of Bielinek, on a grassy SW slope of the Oder v.; leg. J. Mądalski, 21.09.1955 (KRAM, 494779); leg. Exc. Inst. Bot. U. P., 06.1952 (POZ); **BF: 24** – Słoszów, xer. gras. of the alliance *Bromion erecti* on the margin of an old limestone quarry W of Słoszów, (<10), 630 m [86]; Raczyn, overgrowing gras. on the forest margin, *Bromion erecti*, (<100), 700 m [86]; Zielone, thermophilous gras. of the alliance *Bromion erecti* (a few hundred specimens), 680–700 m [87–89]; between Zielone and Słoszów, a belt of dry gras. on the forest margin, (8), 650 m [86,87]; **36** – Śnieżnik Massif, Krowiarki, 0.3 km NW of the summit Kamiennik, SW slope xer. gras. of the alliance *Bromion erecti*, a narrow strip between the cultivated field and spruce forest, (7), 50°19'46" N, 16°43'38" E, 560 m, vid. M. Karakula, det. M. Smoczyk, 17.06.2014 (phot.); 0.3 km to the NW and SE from the top of the mountain Kamiennik, xer. gras. of the *Bromion erecti* and *Trifolion medii* alliances, (7), 550–560 m, vid. M. Karakula, M. Smoczyk, 01.07.2014 (phot.); **CE: 00** – Kaszowo, Milice distr., thermophilous meadow, NW exp. (40), vid. L. Matacz, 23.06.2014 (phot.), **CF: 46** – between Borzysławice and Karchów (Borislawitz u. Ł. Krajewski, 08.08.2010 (KTC), vid. Ł. Krajewski 2010–2011; 46 – Żurada, S of Kolonia I, NE slopes of hill 439, calcareous gras. and scrubs, fallows, field baulks, N exp., (50), 50°14'58" N, 19°32'22" E, 425–430 m, leg. Ł. Krajewski, 13.09.2011 (KTC); 47 – Olkusz NE, hill 423, S slope, baulk between field road and new house, calcareous gras. (20), 50°17'10" N, 19°34'44" E, 415–420 m, leg. Ł. Krajewski, 15.09.2011 (KTC); Kosmolów N, S of Podłużne forest, close to Eagles' Nests red trail, NE slopes of hill 438, dry, sandy meadow, xer. gras. on fallow rendzinias, roadsides, NE, N exp., (60; 500 m E of *O. kochii*'s site), 50°16'48" N, 19°39'29" E, 50°16'52,5" N, 19°39'23" E, 50°16'54" N, 19°39'29" E, 400–420 m, leg. J. Drobnik, 06.07.2001 (KTU, 99021), leg. Ł. Krajewski, 10.07.2011 (KTC) [92]; 51 – Mikołów-Mokre, Fiołkowa Góra hill, (Nikolai: Mokrauer Kalkberg) [93]; dry meadow on N slope, leg. M. Dobrzańska, 28.08.1977 (KTU, 16211); leg. M. Klączek, 01.08.1983 (KTU, 38299) (Babczyńska-Sendek 1998, Urbisz 2001, US); Mikołów, Sośnie Góra (hill 329), gras. areas of the botanical garden, (10), vid. W. Podstolski 06.2013, phot.; 53 – Lędziny SW, Góra Klimont Mt (hill 302), SW of St. Clement church, xer. gras., (very rare, mixed with *O. kochii*), 50°07'13" N, 19°06'08" E, 295 m, leg. Ł. Krajewski, 13.09.2010 (KTC); 54 – between Imielin-Pasieczki and Mysłowice-Dziećkowice, hill 310, calcareous xer. gras., S exp., (15, 250 m to W of *O. kochii* on summit mound), 50°09'55" N, 19°12'11,5" E, 287 m, leg. Ł. Krajewski, 04.09.2010 (KTC); 56 – between Dulowa and Młoszowa, n. Trzebinia, calcareous slope close to road, leg. A. & J. Kornasiowie, 08.08.1955 (KRAM, 014846); 57 – between Wola Filipowska and Krzeszowice, xer. gras. on the border of hamlets Pasternik and Podgórk, on a hillside Skałka, (32), 50°07.230'N, 19°35.893'E, 305 m, leg. B. Binkiewicz, 08.07.2014 (KTC); 64 – Chełm Śląski E, Smutna Góra Mt (hill 285 with cholera cemetery), xer. gras., old limestone quarries, (20), 50°06'30" N, 19°12'44" E, 50°06'26" N, 19°12'50" E, 275–280 m, leg. Ł. Krajewski, 04.09.2010 (KTC), vid. P. Grzegorzek, 07.2014 (phot.); 66 – between Wygielzów and Zagórze, pass between Grodzisko Wielkie and Małe

hills, in *C. scabiosa* population, very abundant, leg. P. Grzegorzek, 10.07.1989 (Grzegorzek private herbarium); 79 – Ochojno Świątniki Górne distr., n. Stronie estate, overgrowing *Festuco-Brometea* gras. with *C. scabiosa*, on a small hill n. houses in the estate, W exp., (Pogórze Wielickie, Western Carpathian Mts), (>40), leg. W. Bartoszek, 15.06.2002 (KRA, 0260657, 0260658, 0260579, 0260586); 78 – cfr., between Rzozów and Radziszów n. Skawina, NW slope of Lipie hill, leg. H. Trzcińska-Tacik, 1980 (KRA); 86 – Wadowice, between road bridge and railway bridge, leg. E. Markiewicz, 19.06.1992 (KTU, 45891); 89 – Siepraw (Sieprawski), S slope, gras., leg. K. Hajduk, 20.09.2009 (KRA); DG: 01 – Tuł, calcareous hill between Goleszów and Leszna (Śląsk Cieszyński), leg. A. Żmuda, (KRAM, 061500); In Getriedefeldern am Tuł bei Ustroń (Schlesien), leg. F. Pax, 06.1888 (BP); Tuł bei Teschen, leg. Fiek, 16.07.1858 (WA, 30506), leg. Fiek, 18.07.1888 (BP), (Silesia, Cieszyn distr., Tuł hill SW of Ustroń town); Tuł [21,54,55,94–97]; vid. M. Śniegoń, 06.2000 (phot.), vid. T. Beczała, 2003 (has not occurred since 2008); EE: 64 – Zachełmie n. Zagnańsk, xer. gras. on the edges of a closed quarry n. Chełmowa hill (<10), 50°58'10" N, 20°41'28" E, 354 m, vid. A. Przemyski, 09.2011 (phot.) [13]; EF: 13 – Góry Pińczowskie Mts, NW of Pińczów, margin of a field and a fallow (3), 50°32'08,4" N, 20°30'46" E, 219 m, leg. R. Piwowarczyk, 09.06.2009 (KTC) [13,14]; Polana Polichno res. n. Młodzawy, xer. gras., oak-hornbeam communities (>8), 50°28'01,9" N, 20°28'06,7" E, 215 m, leg. R. Piwowarczyk, 27.06.2006, (KTC), vid. R. Piwowarczyk, 06.2009 [13]; 70 – Koźmice Wielkie n. Wieliczka, dry gras. *Festuco-Brometea*, at the foot of a mound (Pogórze Wielickie, Western Carpathian Mts), leg. W. Bartoszek, 12.06.2002 (KRA, 0260473, 0260474, 0260484, 0260583, 0260584, 0260585, 0260590) [79]; EG: 05 – cfr., Znamirowice on lake Rożnowskie, W slope of Grochówki [98]; FG: 37 – Myczkowce n. Olszanica, slope on the San river, vid. M. Szewczyk (phot.), 07.06.2012; GE: 45 – Wólka Leszczańska, a narrow belt of xer. gras. between the "Żmudź" res. and the village (>5), 51°00'41" N, 23°39'09" E, leg. P. Chmielewski, R. Piwowarczyk, 08.06.2008 (KTC) [9]; Leszczany, a fallow field and an arable field adjacent to a former limestone excavation pit, by the Żmudź-Kumów Majoracki road, near village buildings (<50). Some specimens were deformed, probably following treatment with weed killers. 51°01'29" N, 23°34'53" E, leg. P. Chmielewski, R. Piwowarczyk, 09.06.2007 (KTC) [9]; 55 – Żmudź, xer. gras. and scrub in the "Żmudź" reserve and along its borders, ca. 0.5 km W of Kolonia Żmudź (>10), 51°00'29" N, 23°40'27" E, leg. R. Piwowarczyk, P. Chmielewski, 08.06.2007 (KTC) [9]; Podlesie, a xer. gras. and blackthorn scrub, ca. 1 km S of Wólka Leszczańska (>20), 51°00'03" N, 23°39'03" E, vid. P. Chmielewski, 2007 [9]; Turowiec, a vast complex of initial xer. gras. and juniper scrub, ca. 1.5 km N of the cemetery near Turowiec and Popówka villages (<5), 50°58'00" N, 23°38'12" E, vid. P. Chmielewski 2007, xer. gras. with *Juniperus communis*, (2), 50 57 59,5N, 23 38 11,9E, vid. R. Piwowarczyk 03.06.2011 [9]; 55/56 – Kolonia Teresin, roadsides, fallow fields, xer. gras. and sparse blackthorn scrub on a vast calcareous scrub ca. 0.5 km S of the village (>30), 50°59'41" N, 23°40'54" E; 50°58'43" N, 23°41'57" E; 50°59'19" N, 23°41'29" E; 50°58'49" N, 23°42'09" E; 50°59'01" N, 23°41'11" E; 50°58'46" N, 23°41'25" E;

50°59'20" N, 23°42'00" E, leg. P. Chmielewski, R. Piwowarczyk, 08.06.2007 (KTC), [9], probably also *O. kochii*; **72** – Chomęcka Małe, a xer. gras. on a hillside, ca. 0.5 km SE of village buildings, at an intersection of field roads (<5), 50°48'26" N, 23°12'34" E, vid. P. Chmielewski, R. Piwowarczyk, 09.06.2007 [9]; **73** – Huszczka Duża, xer. gras. belonging to association *Inuletum ensifoliae* and in communities with *Brachypodium pinnatum*, on a vast calcareous slope (<15), 50°50'10" N, 23°19'11" E, leg. A. Cwener, 30.06.2006 (LBL) [9]; **81** – Niedzielska, fringe communities on the edge of a juniper scrub complex, ca. 700 m S of village buildings (one specimen), 50°42'00" N, 23°04'53" E, vid. A. Cwener, P. Chmielewski, 28.07.2009 [9]; **82** – Kąty II, initial xer. gras. near a dirt road from the Wymysłówka village to Wychody, on a midfield hill known as Wieprzecka Góra (<10), 50°40'46" N, 23°07'35" E; vid. R. Piwowarczyk, W. Michalczuk & P. Chmielewski, 2006 [9]; Kąty n. Zamość, pine forest on humic chalky rendzina, leg. D. Fijałkowski, 05.06.1959 (LBL); sunny chalky slope, leg. D. Fijałkowski, 11.08.1965 (LBL); Kąty II, oak forest on chalk, leg. D. Fijałkowski, 29.06.1951 (LBL); Kąty II n. Zamość, *Inuletum ensifoliae*, leg. A. Brzeg, 04.08.1984 (POZ); vicinity of Zawada n. Zamość, on a baulk between arable fields, field, leg. D. Preferred habitats, plant communities and host

Orobanche elatior and *O. kochii* are clearly distinguished by their phytocoenoses. *Orobanche elatior* prefers sunny hillsides and slopes of hillocks, hills and valleys but also flat areas, infrequently also the colder horizon sector, at altitudes (40)200–400(700) m above sea level. Its highest sites are in the Góry Orlickie Mts (Central Sudetes Mts) and the Silesian Beskid Mts (Western Carpathians). It prefers alkaline soils, usually shallow rendzinas formed on chalk marl and limestone, dolomite, loess, gypsum, and chernozem. The abundance of specimens in populations is usually small and is 5–20 shoots but sometimes only a single inflorescence is noted. The most abundant populations occur in the Sudetes Mts (one site of a few hundreds shoots) [86] and in the central part of the Silesia-Cracow Upland (a few sites with over 100 shoots). Fluctuations in the population size are noticeable at localities observed over a few vegetative seasons.

Orobanche elatior prefers a broad phytocoenotic range. It comprises intermediate communities and is often difficult to classify. This reflects the transitional and mosaic type of habitats colonized by the species and their dynamic-succession condition. *Orobanche elatior* occurs in xerothermic grasslands of the alliance *Cirsio-Brachypodion pinnati* (*Festuco-Brometea* class) and communities of juniper scrub, e.g. in the Lublin Land. The species also often occurs in abandoned fields, fallows or wastelands, roadsides, along railways, in intermediate communities between xerothermic grasslands (*Festuco-Brometea*, *Festucetalia valesiacae*), thermophilous meadows (*Molinio-Arrhenatheretea*, *Arrhenatheretalia*), pioneer semiruderal xerothermic communities (*Agropyretea intermedio-repentis*) and ruderal communities (*Artemisieta vulgaris*, *Onopordetalia*, suballiance *Dauco-Melilotenion*, especially *Dauco-Picridetum hieracioidis*, and *Echio-Melilotum* associations). It is fairly frequently recorded in fringe communities of the alliance *Geranion sanguinei* (*Trifolio-Geranietae* class). *Orobanche elatior* is also encountered within or on the margins of cultivations of, e.g. rape, cereal crops, or on the margins and baulks of calcareous fields, with a contribution of species of the alliance *Centauretalia cyanii*, e.g. *Caucalidion lappulae* (*Stellarietea mediae* class) (Appendix S1). In the Sudetes Mts, the species was noted in thermophilous grasslands on forest margins of the alliance *Bromion erectii* [86].

Orobanche kochii prefers sunny sites, usually gentle S or SW-facing slopes but it is also found at N facing or flat sites; altitude about (40)200–400(430) m. These include xerothermic grasslands, thermophilous shrublands; located on slopes of hills, river valleys, gullies, margins of forests and fields, in former quarries, baulks, fallows and ruderal sites. It prefers alkaline soils, usually shallow rendzinas formed on chalk marl and limestone, dolomite, loess, and

chernozem (black-earth soil). It is recorded most frequently in communities of the alliance *Cirsio-Brachypodion pinnati* (class *Festuco-Brometea*), especially on flowery or initial dry grasslands, i.e. *Adonido-Brachypodietum pinnati*, *Inuletum ensifoliae*, *Thalicstro-Salvietum pratensis*, and on hills, in former gypsum excavation pits in the Nida Basin, also in *Seslerio-Scorzonerogetum purpureae*, and in the community *Carex glauca-Tetragonalobus maritimus*. In the Silesia-Cracow Upland it occurs mostly on strongly xerothermic fallow rendzinas and on secondary calcareous grasslands formed close to old limestone quarries, usually on steep slopes, less frequently in slightly thermophilous north-facing associations. In the Cracow-Częstochowa Upland, the species also sometimes grows in the ecotone of rocky grasslands at foothills of limestone mogotes (*Festucetum pallentis*) and thermophilous scrub (*Geranion sanguinei*), usually in the association *Origano-Brachypodietum pinnati*. As a result of natural plant succession in grasslands, the communities have a high contribution or a mosaic of species of thermophilous herbaceous forest edge communities of the alliance *Geranion sanguinei* (class *Trifolio-Geranietae sanguinei*) and shrub communities, particularly of the alliance *Berberidion* (class *Rhamno-Prunetea*), as well as xeric meadow species of the alliance *Arrhenatherion elatioris* (class *Molinio-Arrhenatheretea*). The species is also often encountered on former fallows and wastelands, especially in rendzina soil conditions, in communities of the class *Artemisieta vulgaris* with a high contribution of xerothermic and meadow species (Appendix S2). The abundance of populations varies greatly and ranges from year to year. Its populations are more abundant than those of *O. elatior* and comprise 15 shoots on average, rarely app. 100–250, e.g. 100 Gartatowice, 150 (Wojkowice) and 250 (between Wojsławice and Cynków). The abundance behaviour of *O. kochii* is similar to that of *O. picridis* [14]. It rapidly and densely colonizes abandoned areas after which its number drops suddenly as a result of succession changes. However, in the central part of the Silesia-Cracow Upland, the majority of its localities are less numerous (also less numerous than *O. elatior*), and sometimes only single specimens could be found. At these sites the species is difficult to find (in dry forms), especially because specimens are often very sparse in other *Orobanche*, mostly in the much more numerous *O. lutea*. All the communities mentioned above include a high contribution of host species of *C. scabiosa*, with the coverage being about (5)25(50)% (Appendix S1, Appendix S2).

Discussion

Orobanche kochii is more common and widely distributed in Poland, the Czech and Slovak Republics, and in much of Central Europe, with the distribution area shifting from central Europe towards Eastern Europe and Asia. *Orobanche elatior* is noticeably scarcer in Central Europe and its distribution is confined to Western and Central Europe. Their ranges overlap in Central Europe.

A revision of herbarium materials and field investigations into *O. elatior* and *O. kochii* in Poland was conducted between 1999 and 2014. Considerable differences in the

distribution were found, especially in relation to the previous distribution map of *O. elatior* s.l. in Poland [70] and in Central Europe [21]. At present *O. elatior* occurs in Poland mainly in the Silesia-Cracow, Małopolska and Lublin Uplands, rarely in the Lower Vistula Valley, Central Sudetes Mts, Western Carpathian Mts and Carpathian Foothills. *Orobanche kochii*, which is definitely more common than *O. elatior*, has numerous localities especially in the Polish Uplands: Silesia-Cracow and Małopolska Uplands, and Lublin-Lviev, Volhynia Uplands, Roztocze and Polesie (Fig. 3, Fig. 4). Our research demonstrated that *O. kochii* and *O. lutea* are the most common representatives of this genus in Poland.

The abundance of populations of *O. elatior* and *O. kochii* varies greatly by region in Poland and fluctuates considerably in individual years. The both taxa are monophagous species and in Poland, like in other countries of Central Europe, they are parasitic on *C. scabiosa*.

Zázvorka [21] stated that *O. kochii* and *O. elatior* had never been found growing together at the same site, but they sometimes occur together in Poland (e.g. DG-Błędów, DG-Łosy, DG-Gołonóg, Podskale, Jaworzno-Cieżkowice, Lędziny, Imielin/Mysłowice).

The new form described as *O. kochii* f. *citrina*, and found in the populations of typical individuals, within the same habitat conditions, was previously known from Poland only, but may possibly be identified in a wider geographical range. We still need to confirm the cream color forms described as *O. kochii* and presented in photographs taken in the Crimea (Tepe-Oba Mts near Teodosia and Mys Fiolent), without any certain information on a host plant (<http://www.plantarium.ru>). However, herbarium materials at LE from the Crimea (Mys Fiolent) include individuals of *O. ritro*, parasitizing *Echinops ritro* [20], with a characteristic creamy or less common yellow color of corolla [27,62]. Many species of the genus *Orobanche*, e.g. *O. alba*, *O. alsatica* s.l., *O. caryophyllacea*, *O. hederae*, *O. laxissima* group, are often lighter in color than the typical, commonly occur form, but these forms almost never constitute the majority of a population. Such pigmentation is not typical and sometimes may also result from low insolation, soil pH, hosts, or incomplete plant pigmentation. Yellow and albinotic forms usually occur in shaded sites [10–12,68,131–133], but sometimes also in places exposed to strong sunlight.

The role of seed features in the identification of species *Orobanche* to relate such characters to the systematics of the group, have been presented in several studies (e.g. [11,40,68,132,134,135]). The use of micromorphological characters, i.e. seed and pollen ornamentation (SEM) or a cross-section of the exine of dust seeds (TEM), have revealed additional differences between related species of *O. alsatica* agg. (*O. alsatica*, *O. bartlingii*, *O. mayeri*) [132]. Concerning the seeds of the investigated species, the best taxonomic character is the diameter and the shape of wall perforations. In *O. elatior* the perforation diameter is much larger, 4–13 µm, and is usually elliptical, while in *O. kochii* the diameter is smaller, 2–4 µm, and subcircular. The size and shape of seeds is less important for species identification. The position of a very large number of seeds in the ovary may also determine their shape as well as that of their

cells [19,136]. Palynological analysis also revealed auxiliary micromorphological subtle differences in the size and level of sculpture of pollen grains between both species [137]. Differences in morphology, preliminary molecular studies, seed and pollen sculpture, and some ecological preferences confirm the separation of the examined taxa at species level.

Orobanche elatior s.l. is a partially protected species in Poland (regulation 2014). It is not a common species and is included on the “Red list of vascular plants in Poland” as rare – R [138] and vulnerable (VU) in the Carpathian Mts [79]. It is also included on regional red lists and books: Gdańsk Pomerania, CR, Western Pomerania, E [139,140]; Western Pomerania and Wielkopolska, E [139]; Wielkopolska, CR [141]; Sudetes Mts, CR [142]; Opole province, CR [56], endangered, EN, in the Lower Silesia province [143], Kujawy-Pomerania region, I (indeterminate) [144], Małopolska Upland, VU [145]. The species is also vulnerable in neighboring countries, i.e. Germany [146,147], the Czech Republic [148] and Slovakia [149]. These threat categories require revision as they concern *O. elatior* s.l., which contained the rare *O. elatior* and considerably more common *O. kochii*. Both species are included together only in the vascular plant red list of the Silesia province (*O. elatior* – category VU, vulnerable and *O. kochii* – NT, near threatened) [150], coauthored by us.

The progressing process of secondary succession of tree- and shrub vegetation, the density of the herb layer and the cessation of former cultivation methods, especially the loss of grazing, are the main threats to both species. Their sites are often found near arable fields where they are exposed to chemical agents. *Orobanche elatior* is especially vulnerable as it often prefers habitats in the ecotone of arable fields, and tetralogic and deformed forms affected by weed-killing agents are often observed. Similarly due to the impact of EU subsidies on cultivation profitability, *O. kochii* localities on old fallows are reploughed. Land development is a direct threat in many cases as the species' habitats are often in scenic landscapes that are demanded for housing estates, especially in the central part of the Silesia-Cracow Upland, where numerous localities of both *O. kochii* and *O. elatior* are now on the margin of one of the largest European conurbations. Some localities are on the edge of operating, expanding quarries. A part of the population of *O. kochii* on the dolomite quarry in the DG-Ząbkowice has disappeared in this way. The arrival of invasive or expansive species also poses a considerable threat. *Heracleum sosnowskyi* has been moving worryingly close to its population. Mass self-sowing of *Solidago canadensis*, *S. gigantea* and *Calamagrostis epigejos* is observed at many sites. Only a few localities are protected: *O. elatior* – Bieliniek res. (not confirmed here for many years), Gipsowa Góra hill, Machnowska Góra hill, Polana Polichno; *O. kochii* – Zimne Wody, Żmudź, Murawy Dobromierskie, Biała Góra hill, Skarpa Dobużańska, Rogów, Opalonki, Przęślin, Skorocice, Krzyżanowice, Skotniki Górnne; also protected as ecological sites or within Natura 2000 sites. This does not ensure the preservation of the species as active protection is needed. Many localities are at disturbed sites or at operating excavation sites (limestone, gypsum). At least some of the localities should be protected as ecological sites and active protection measures should be implemented:

mowing or grazing of excessively developing field- and herbaceous vegetation, while preserving the unique mosaic systems and fringe communities, and nature monitoring. The abundance of the host species *C. scabiosa* should also be monitored as this is usually neglected or overlooked in the protection of parasitic plants. Special attention should be paid to the sites where *O. kochii* and *O. elatior* co-occur

or have been recorded for a very long time (Góra Gipsowa Mt 1841–2010, Góra Tuł hill 1858–2008, between Pasieczki and Dziećkowice 1863–2010), or localities usually indicating exceptionally well-preserved patches of xerothermic grasslands, including other rare *Orobanche* species (*O. lutea*, *O. bartlingii*, *O. picridis*, *O. caryophyllacea*, *O. alsatica*).

Acknowledgments

The author thanks the curators of herbaria and other persons who kindly made their data on the species available. We are also grateful for the assistance during field studies. Special thanks are due to Jiri Zázvorka for invaluable comments and discussion and to Beata Babczyńska-Sendek for our field excursions and for providing access to the University of Silesia *Orobanche* database. This work was supported by the Polish Ministry of Science [grant No. NN303357733 (2008–2009), NN303551939 (2010–2013)] and partially Principal Research Project 612419 (2014–2015).

Authors' contributions

The following declarations about authors' contributions to the research have been made: concept of the study: RP; herbarium revision: RP; micromorphology of seeds, taxonomy and phytosociological analysis: RP; writing the manuscript and field research: RP, ŁK.
